

## • Creating 2D array in Python

When we have a list in python  
`ls = [1, 1, 1]`. Python does not  
 create 3 integer objects,  
 separately. Instead only one object  
 is created.

↳ In python  
 if content  
 is same  
 address  
 is same)

`arr = [[1, 2]] * 3`  
`= [[1, 2], [1, 2], [1, 2]]`

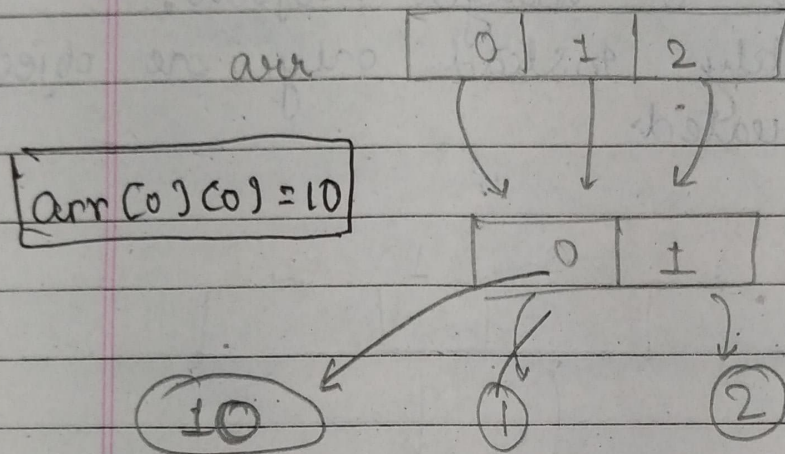

(This will create a hollow list)

All the indices of arr are pointing towards 'same nested list'.

$$\text{id}(\text{arr}[0]) = \text{id}(\text{arr}[1]) = \text{id}(\text{arr}[2])$$

$$\text{arr} = \left[ [10, 2], [10, 2], [10, 2] \right]$$

we changed only one element.  
 Why did this happen? Because  
 there was 'one common list'.  
 For all the indices.

change in one row affected  
 all rows

- $arr = [ [j \text{ for } j \text{ in range}(1,3)] \text{ for } i \text{ in range}(3)]$   
 $arr = [ [1, 2], [1, 2], [1, 2] ]$

All the indices of 'arr' are pointing towards different nested lists.

$id(arr[0]) \neq id(arr[1]) \neq id(arr[2])$

$arr[0][0] = 10$

$arr = [ [10, 2], [1, 2], [1, 2] ]$

Modifying one row (list) did not affect other rows. As, all the lists were unique.
